Abstract—For the turbo code (TC) consisting of recursive systematic convolutional (RSC) codes, the complete knowledge of the low-weight codewords of the RSC code is very important for interleaver design in order to achieve good TC performance. In this paper, we present a method to determine the patterns of low-weight codewords for RSC codes. For a given RSC code, we first identify the codewords with weight-2 and weight-3 parity-check components (PCs) based on the characteristic of the feed-forward polynomial. Similarly, we identify the codewords with low-weight systematic components (SCs) based on the feedback polynomial, and then establish the low-weight codewords from the identified codewords. To validate our proposed method, we obtain a union bound using the established low-weight codewords and compare it with that obtained via the transfer function method and the bit error rate (BER) curve drawn from simulation results.

I. INTRODUCTION

The TC [1], introduced by Claude Berrou in 1993, is one of the *forward-error correcting* (FEC) codes that comes very close to satisfying the Shannon limit for AWGN channels. Due to its excellent performance, TCs have been adopted by many industrial standards. [2], [3], [4].

The TC is generally constructed by concatenating two RSC codes (usually of the same kind) parallelly via an interleaver. A well designed TC realizes a large minimum distance via the interleaver, if it maps each bit sequence with a low-weight PC in the first RSC code onto that with a high-weight PC in the second RSC code. Thus, the design of a good deterministic interleaver requires the complete knowledge of all the low-weight codeword component patterns of the employed RSC code and missing even one of these patterns may result in TC with subpar error correction performance.

The transfer function of an RSC code is an interleaver design tool that provides information about the different weights in the code, as well as their corresponding multiplicities (distance spectrum). However, it provides no information with regards to the pattern of the low-weight codeword components. As an added downside, the complexity of calculating the transfer function for a given RSC code increases with the number of states, and other methods such as Mason's Rule [5] have to be used. Research into other methods for finding the distance spectrum have been carried out in recent years. In [6], an

algorithm for evaluating the input-parity weight distribution of terminated RSC codes is presented, while in [7], the distance spectrum of tail-biting duo-binary RSC codes is calculated using the modified FAST algorithm. These methods also do not reveal the pattern of the low-weight codeword components and to the best of our knowledge, there exists no interleaver design tool that provides complete knowledge of the low-weight codewords. Because of this, many of the interleaver design methods end up completely ignoring certain important low-weight codewords. In [8] for example, the interleaver design method does not take into account the existence of low-weight codewords with systematic components of weight 3, especially for the 5/7 RSC code, where such codewords are dominant.

In this paper, we propose a method for revealing the pattern of the low-weight codeword components. The complexity of our proposed method is independent of the number of states of the RSC code and its ability to reveal the low-weight codeword patterns of an RSC code makes it an excellent interleaver design tool. We establish the low-weight codewords for the given RSC code by identifying codewords with either PCs or SCs of weight-2 and weight-3. Then, using the established low-weight codewords, we validate our proposed method by obtaining a union bound and comparing it to that obtained via the transfer function method and the BER curve obtained via simulation results.

The remainder of the research paper is organised as follows. Definitions used in this paper are introduced in Section II. In Section III, we discuss the characteristics of the low-weight RSC codewords and then present our method in Section IV. Validation of our proposed method for specific RSC codes as well as discussion of numerical results is done in Section V and the paper concludes in Section VI.

II. PRELIMINARIES

A polynomial in x with degree M is an expression of the form

$$v(x) = \sum_{m=0}^M v_m x^m \quad (1)$$

where $v_M \neq 0$ and v_m , $0 \leq m \leq M$, are called the *coefficients*. If $v_M = 1$, $v(x)$ is called a *monic* polynomial. We say the total number of the non-zero coefficients of $v(x)$ is the *Hamming weight* of $v(x)$, denoted as $w_H(v(x))$.

For a prime number p , if the addition and multiplication of two elements in the integer set $\{0, 1, p-1\}$ are performed on the terms mod p , we call the set a Galois field, denoted as $\text{GF}(p)$. If the coefficients in (1) are elements of $\text{GF}(p)$, $v(x)$ is called a *polynomial over* $\text{GF}(p)$.

For two polynomials $v(x)$ and $w(x)$ with degrees M and N , respectively, the addition and multiplication over $\text{GF}(p)$ are defined as

$$v(x) + w(x) = \sum_{m=0}^{\max\{M,N\}} [(v_m + w_m) \bmod p] x^m \quad (2)$$

and

$$v(x)w(x) = \sum_{m=0}^{M+N} \sum_{i=0}^m [v_i w_{m-i} \bmod p] x^m \quad (3)$$

respectively.

We say a monic polynomial is a *prime polynomial* if it cannot be represented by multiplication of some lower degree polynomials. For two polynomials $v(x)$ and $w(x)$ over $\text{GF}(p)$, $w(x) \neq 0$, there exists polynomials $q(x)$ and $r(x)$ over $\text{GF}(p)$ such that

$$v(x) = w(x)q(x) + r(x) \quad (4)$$

with $\deg(r(x)) < \deg(w(x))$. We represent $r(x)$ in the expression (4) as

$$r(x) \equiv v(x) \bmod w(x) \quad (5)$$

and call it the *remainder polynomial*, while $q(x)$ is called the *quotient polynomial* of the division of $v(x)$ by $w(x)$.

Let $v(x)$ be a prime polynomial over $\text{GF}(p)$ with $\deg(v(x)) := M > 1$ and \mathcal{V} be the polynomial set of size p^M containing all polynomials over $\text{GF}(p)$ with degree less than M . Then, the *extension field* of $\text{GF}(p)$, denoted by $\text{GF}(p^M)$, is the set \mathcal{V} with addition and multiplication over $\text{GF}(p)$, where the multiplication is carried out modulo $v(x)$ over $\text{GF}(p)$. Each non-zero element in $\text{GF}(p^M)$ can be represented by a power of x uniquely as x^m , $0 \leq m \leq p^M - 1$.

For each non-zero element of $\text{GF}(p^M)$, there exist integers ϵ such that $x^\epsilon = 1$ and the least positive integer among them is called the *order* of x . We say that elements with order $\epsilon = p^M - 1$ are *primitive elements*. For $\text{GF}(p^M)$ generated by a prime polynomial $v(x)$ with $\deg(v(x)) = M$, if x is a primitive element in $\text{GF}(p^M)$, then $v(x)$ is called a *primitive polynomial*. Finally, the root of $v(x)$, is the non-zero element φ , $\varphi \in \text{GF}(p^M)$ such that $v(\varphi) = 0$. If $v(x)$ is a primitive polynomial, the order of φ is $\epsilon = p^M - 1$, otherwise $\epsilon | p^M - 1$, i.e. ϵ divides $p^M - 1$. Moreover, the elements φ^i , $0 \leq i \leq \epsilon - 1$, are all distinct from each other.

III. THE CHARACTERISTICS OF THE LOW-WEIGHTS CODEWORDS OF RSC CODE

The outputs of an RSC code are determined by the input bit sequence $b(x)$, states of the shift registers and feedforward and feedback connections of the shift registers that can be represented by a generator function.

As an instance, the generator function of a rate 1/2 RSC code may be written as

$$\begin{bmatrix} 1 & \frac{f(x)}{g(x)} \end{bmatrix}$$

where 1 yields the *systematic component* (SC) $b(x)$ while the *parity-check component* (PC) $h(x)$ is associated with the feedforward and feedback connections of the shift registers, specified by $f(x)$ and $g(x)$, respectively. The output $c(x)$ is the mixture of the SC and PC as

$$c(x) = b(x^2) + xh(x^2) \quad (6)$$

where

$$h(x) = f(x)g^{-1}(x)b(x) \quad (7)$$

From (6), it is trivial that

$$w_H(c(x)) = w_H(b(x)) + w_H(h(x)) \quad (8)$$

and hence, each low-weight codeword is combination of low-weight SC and PC.

Under the assumption of large frame sizes, the presence of $g^{-1}(x)$ in (7) may involve a particular bit sequence that repeats a large number of times, hence yielding a high-weight PC. Therefore, low-weight PCs occur if and only if

$$b(x) \bmod g(x) \equiv 0 \quad (9)$$

The bit sequences satisfying (9) are called *return-to-zero* (RTZ) input. Thus, every RTZ input can be factorized as

$$b(x) = a(x)g(x) \quad (10)$$

and, substituting (10) into (7), we can characterize the low-weight PC as

$$\begin{aligned} h(x) &= f(x) \cdot g^{-1}(x) \cdot a(x)g(x) \\ &= a(x)f(x) \end{aligned} \quad (11)$$

Therefore, in this paper, we attempt to find $a(x)$ s satisfying (10) and (11) simultaneously for low-weight $b(x)$ and $h(x)$, respectively. However, since there is no essential mathematical difference between the two equations, in the next section, we present a method for determining the low-weight PC patterns for $w_H(h(x)) = 2, 3$.

IV. THE PATTERNS OF THE LOW-WEIGHT PCs

We assume $f(x)$ can be factorized into K prime polynomials as

$$f(x) = \prod_{k=0}^{K-1} f_k^{\gamma_k}(x) \quad (12)$$

where $\gamma_0, \gamma_1, \dots, \gamma_{K-1}$ are positive integers and let φ_k be a root of $f_k(x)$ of order ϵ_k . After that, we consider the solution of

$$h(x) \bmod f(x) \equiv 0 \quad (13)$$

We start from the simplest case $K = 1$, i.e., $f(x) = f_0^{\gamma_0}(x)$. Then, (11) indicates that each root of $f(x)$ is also the root of $h(x)$ and we distinguish the cases $\gamma_0 = 1$ and $\gamma_0 > 1$. For the former case, since all φ_0^i , $0 \leq i < \epsilon_0$, are distinct from each other, the equation

$$h(\varphi_0^i) = 0, \quad 0 \leq i < \epsilon_0 \quad (14)$$

is a necessary and sufficient condition of (13) while it is necessary but not sufficient for the latter case. Thus, for the case $\gamma_0 > 1$, we obtain extra conditions using differential equations as

$$\left. \frac{d^{(j)} h(x)}{dx^j} \right|_{x=\varphi_0^i} = 0, \quad 0 \leq i < \epsilon_0, \quad 1 \leq j < \gamma_0 \quad (15)$$

where the derivation is calculated using the *Hasse derivative* defined as

$$\frac{d^j x^k}{dx^j} = \begin{cases} (k C_j \bmod 2) x^{k-j}, & k \geq j \\ 0, & \text{otherwise} \end{cases} \quad (16)$$

for the binomial coefficient $k C_j$.

For the case where $K > 1$, we may repeat the above discussion for the roots φ_k , $0 < k < K$, and take the intersection of the results to determine the low-weight PCs.

A. The weight-2 PCs

Each weight-2 PC can be written as

$$h(x) = 1 + x^\alpha \quad (17)$$

without loss of generality. Thus, we have from (14) that

$$(\varphi_0^i)^\alpha = 1, \quad 0 \leq i < \epsilon_0 \quad (18)$$

On the other hand, the order of φ_0 is the least positive integer satisfying $\varphi_0^{\epsilon_0} = 1$. Thus, α should satisfy the condition

$$\alpha \equiv 0 \bmod \epsilon_0 \quad \text{or} \quad \epsilon_0 | \alpha \quad (19)$$

B. The weight-3 PCs

Without loss of generality, the weight-3 PCs can be written as

$$h(x) = 1 + x^\alpha + x^\beta, \quad \alpha < \beta \quad (20)$$

and hence, (α, β) should satisfy the condition

$$\varphi_0^\alpha + \varphi_0^\beta = 1 \quad (21)$$

The pairs (α, β) satisfying (21) can be found by referring to the table of the extended field for $\text{GF}(2^M)$. Let (m, n) be such a pair and let $\mathbb{M} = \{\epsilon_0 \ell + m\}_{\ell \in \mathbb{Z}}$ and $\mathbb{N} = \{\epsilon_0 \ell + n\}_{\ell \in \mathbb{Z}}$, where \mathbb{Z} represents the set of non-negative integers. Then it is obvious that each pair $(\alpha, \beta) \in \mathbb{M} \otimes \mathbb{N}$ satisfies (21), where $\mathbb{M} \otimes \mathbb{N}$ denotes the tensor product that yields the set consisting of all pairs of \mathbb{M} and \mathbb{N} sorted in ascending order. For a fixed α , on the other hand, since $\alpha + i$, $0 \leq i < \epsilon_0$, are distinct from each other, any integer β that satisfies (21) must be such that $n \equiv \beta \bmod \epsilon_0$.

C. Examples

In the following, we present some examples of the proposed method to determine weight-2 and weight-3 PCs for several feedforward polynomials of form given in (12). For the case $K = 1$, Examples 1 and 2 are two instances where $f(x)$ is a primitive polynomial while an instance where $f(x)$ is prime but not a primitive polynomial is given in Example 3. Example 4 demonstrate the case $\gamma_0 > 1$, and Examples 5 and 6 are two instances of the case $K = 2$. Some weight-2 and weight-3 $h(x)$ are compiled in Table II with their corresponding $a(x)$ for reference.

1) $f(x)$ is a primitive polynomial:

Example 1. $f(x) = 1 + x + x^2$

Since $x^1 = x$, $x^2 \equiv 1 + x \bmod f(x)$, and $x^3 \equiv 1 \bmod f(x)$, $f(x)$ is a primitive polynomial with a root of order $\epsilon_0 = 3$. Thus, α in the weight-2 PCs shown in (17) should be a multiple of 3 as $h(x) = 1 + x^{3\ell}$, $\ell \in \mathbb{Z}^+$, where \mathbb{Z}^+ represents the set of positive integers, while the corresponding $a(x)$ can be expressed by

$$a(x) = \sum_{i=0}^{\ell-1} x^{3i} (1 + x)$$

To determine the weight-3 PCs, we can see from Table I that there is a pair $(1, 2)$ satisfying $x^1 + x^2 \equiv 1 \bmod f(x)$. Thus, let $\mathbb{M} = \{3\ell + 1\}_{\ell \in \mathbb{Z}}$ and $\mathbb{N} = \{3\ell + 2\}_{\ell \in \mathbb{Z}}$. Then, we have $x^\alpha + x^\beta \equiv 1 \bmod f(x)$ for each $(\alpha, \beta) \in \mathbb{M} \otimes \mathbb{N}$.

TABLE I: Non-zero Elements of $\text{GF}(2^2)$ generated by $f(x) = 1 + x + x^2$

power representation	polynomial representation
$x^0 = x^3 = 1$	1
x	x
x^2	$1 + x$

Example 2. $f(x) = 1 + x + x^4$

Since $f(x)$ is a primitive polynomial with a root of order $\epsilon_0 = 2^M - 1 = 15$, the weight-2 PCs have the form $h(x) = 1 + x^{15\ell}$ while the corresponding $a(x)$ can be expressed as

$$a(x) = \sum_{i=0}^{\ell} x^{15i} (1 + x + x^2 + x^3 + x^5 + x^7 + x^8 + x^{11})$$

For the weight-3 PCs, it can be confirmed that there are 7 (m, n) pairs which satisfy $x^m + x^n \equiv 1 \bmod 15$. Thus, $(\alpha, \beta) \in \bigcup_{i=0}^6 \mathbb{M}_i \otimes \mathbb{N}_i$ satisfies (20), where

$$\begin{aligned} \mathbb{M}_0 &:= \{15\ell + 1\}_{\ell \in \mathbb{Z}}, \quad \mathbb{N}_0 := \{15\ell + 4\}_{\ell \in \mathbb{Z}} \\ \mathbb{M}_1 &:= \{15\ell + 2\}_{\ell \in \mathbb{Z}}, \quad \mathbb{N}_1 := \{15\ell + 8\}_{\ell \in \mathbb{Z}} \\ \mathbb{M}_2 &:= \{15\ell + 3\}_{\ell \in \mathbb{Z}}, \quad \mathbb{N}_2 := \{15\ell + 14\}_{\ell \in \mathbb{Z}} \\ \mathbb{M}_3 &:= \{15\ell + 5\}_{\ell \in \mathbb{Z}}, \quad \mathbb{N}_3 := \{15\ell + 10\}_{\ell \in \mathbb{Z}} \\ \mathbb{M}_4 &:= \{15\ell + 6\}_{\ell \in \mathbb{Z}}, \quad \mathbb{N}_4 := \{15\ell + 13\}_{\ell \in \mathbb{Z}} \\ \mathbb{M}_5 &:= \{15\ell + 7\}_{\ell \in \mathbb{Z}}, \quad \mathbb{N}_5 := \{15\ell + 9\}_{\ell \in \mathbb{Z}} \\ \mathbb{M}_6 &:= \{15\ell + 11\}_{\ell \in \mathbb{Z}}, \quad \mathbb{N}_6 := \{15\ell + 12\}_{\ell \in \mathbb{Z}} \end{aligned} \quad (22)$$

2) $f(x)$ is a prime but not primitive polynomial:

Example 3. $f(x) = 1 + x + x^2 + x^3 + x^4$

From [9], since $x \equiv x^5 \pmod{f(x)}$, $\epsilon_0 = 5 < 15$ and the weight-2 PCs can be expressed as $h(x) = 1 + x^{5\ell}$, $\ell \in \mathbb{Z}^+$. For weight-3 PCs, on the other hand, there is no pair (m, n) satisfying $x^m + x^n \equiv 1$, and hence, the given $f(x)$ does not yield any weight-3 PCs.

3) $K = 1$ and $\gamma_0 > 1$:

Example 4. $f(x) = 1 + x^2$ and $f(x) = 1 + x^4$

If we rewrite the polynomials as $f(x) = (1 + x)^2$ and $f(x) = (1 + x)^4$, the order of the root φ_0 is $\epsilon_0 = 1$. Thus, each $\alpha \in \mathbb{Z}^+$ should satisfy

$$h(x) = 1 + x^\alpha = 0 \quad (23)$$

However, the following second order differential equation

$$\frac{dh(x)}{dx} = (\alpha \pmod{2})x^{\alpha-1} = 0 \quad (24)$$

implies α should be an even number. Therefore, for the case $f(x) = 1 + x^2$, we write the PCs as $h(x) = 1 + x^{2\ell}$, $\ell \in \mathbb{Z}^+$.

For the case $f(x) = 1 + x^4$, from (15), we have

$$\begin{cases} \frac{d^2 h(x)}{dx^2} = \left[\frac{\alpha(\alpha-1)}{2} \pmod{2} \right] x^{\alpha-2} = 0 \\ \frac{d^3 h(x)}{dx^3} = \left[\frac{\alpha(\alpha-1)(\alpha-2)}{6} \pmod{2} \right] x^{\alpha-3} = 0 \end{cases} \quad (25)$$

and $\alpha = 4\ell$, $\ell \in \mathbb{Z}^+$, satisfies (25) simultaneously.

Since GF(2) has single non-zero element, it does not provide a pair (m, n) satisfying $x^m + x^n = 1$ and, consequently, there are no weight-3 PCs associated with $f(x)$.

4) *The case $K = 2$:* For this case, we write the feedforward polynomial as $f(x) = f_0(x)f_1(x)$ and give two examples.

Example 5. $f(x) = (1 + x)(1 + x + x^3) = 1 + x^2 + x^3 + x^4$

Let $f_0(x) = 1 + x$ and $f_1(x) = 1 + x + x^3$. We know that the PCs associated with $f(x)$ are intersection of those with $f_0(x)$ and with $f_1(x)$. Since $f_0(x)$ does not yields any weight-3 PCs as explained in the Example 4, there are no such PCs associated with $f(x)$.

With respect to the weight-2 PCs, from Example 4, $\epsilon_0 = 1$ and $\epsilon_1 = 7$. We have the least common multiple of ϵ_0 and ϵ_1 , denoted by $\text{lcm}(\epsilon_0, \epsilon_1) = 7$ and $h(x) = 1 + x^{7\ell}$ with the corresponding $a(x)$ given by

$$a(x) = \sum_{i=0}^{\ell-1} x^{7i}(1 + x^2 + x^3)$$

Example 6. $f(x) = (1 + x + x^2)(1 + x^2 + x^3) = 1 + x + x^5$

For this case, it is not difficult to see that $\epsilon_0 = 3$ and $\epsilon_1 = 7$ for $f_0(x) = 1 + x + x^2$ and $f_1(x) = 1 + x^2 + x^3$, respectively. Thus, from $\text{lcm}(\epsilon_0, \epsilon_1) = 21$, the weight-2 PCs

have the general form of $h(x) = 1 + x^{21\ell}$, $\ell \in \mathbb{Z}^+$, while the corresponding $a(x)$ can be expressed as

$$a(x) = \sum_{i=0}^{\ell-1} x^{21i}(1 + x^2 + x^3 + x^4 + x^6 + x^8 + x^4 + x^6 + x^8 + x^{11} + x^{12} + x^{16})$$

In order to determine weight-3 PCs, we rewrite \mathbb{M} and \mathbb{N} in Example 1 as \mathbb{M}^0 and \mathbb{N}^0 , respectively, and referring to the GF(2³) table, let

$$\begin{aligned} \mathbb{M}_0^1 &:= \{7\ell + 1\}_{\ell \in \mathbb{Z}}, \quad \mathbb{N}_0^1 := \{7\ell + 5\}_{\ell \in \mathbb{Z}} \\ \mathbb{M}_1^1 &:= \{7\ell + 2\}_{\ell \in \mathbb{Z}}, \quad \mathbb{N}_1^1 := \{7\ell + 3\}_{\ell \in \mathbb{Z}} \\ \mathbb{M}_2^1 &:= \{7\ell + 4\}_{\ell \in \mathbb{Z}}, \quad \mathbb{N}_2^1 := \{7\ell + 6\}_{\ell \in \mathbb{Z}} \end{aligned} \quad (26)$$

Then, we have

$$(\alpha_0, \beta_0) \in \mathbb{M}^0 \otimes \mathbb{N}^0$$

and

$$(\alpha_1, \beta_1) \in \bigcup_{i=0}^2 \mathbb{M}_i^1 \otimes \mathbb{N}_i^1$$

Therefore, by taking the intersection, we can identify $(\alpha, \beta) \in (\mathbb{M}^0 \otimes \mathbb{N}^0) \cap \left(\bigcup_{i=0}^2 \mathbb{M}_i^1 \otimes \mathbb{N}_i^1 \right)$.

V. VALIDITY CONFIRMATION THROUGH UNION BOUND

In this section, in order to confirm the validity of our proposed method, we obtain a union bound using the low-weight codewords with weight-2 and weight-3 PC or SC and compare it with that obtained via the transfer function as well as simulation results.

A. A novel union bound

Let $\mathbb{A}_h(d)$ be the set of all $a(x)$ which yields weight- d PCs i.e., $w_H(h(x)) = w_H(a(x)f(x)) = d$. Similarly, we also define $\mathbb{A}_b(d)$ and $\mathbb{A}_c(d)$ as the sets of all $a(x)$ s which result in weight- d SCs and codewords, respectively.

Then, for $w_H(b(x)), w_H(h(x)) \geq 2$, we have from (8) that

$$\mathbb{A}_c(d) = \bigcup_{\ell=2}^{d-2} \{\mathbb{A}_b(\ell) \cap \mathbb{A}_h(d-\ell)\} \quad (27)$$

Now, we replace the set $\mathbb{A}_c(d)$ by the following approximated set

$$\begin{aligned} \mathbb{A}_c(d) \approx \mathbb{A}'_c(d) &= \left\{ \bigcup_{\ell=2}^{\ell+1} \{\mathbb{A}_b(\ell) \cap \mathbb{A}_h(d-\ell)\} \right\} \\ &\quad \bigcup \left\{ \bigcup_{\ell=2}^{\ell+1} \{\mathbb{A}_b(d-\ell) \cap \mathbb{A}_h(\ell)\} \right\} \end{aligned} \quad (28)$$

and obtain an approximated union bound as

$$P_b \leq \frac{1}{k} \sum_{d=d_{\text{free}}}^{d_{\text{free}}+1} \sum_{a(x) \in \mathcal{A}'_c(d)} w_H(a(x)g(x)) Q\left(\sqrt{\frac{2dE_c}{N_0}}\right) \quad (29)$$

Notice that since $\mathbb{A}_c(d)$ in (27) is replaced by $\mathbb{A}'_c(d)$, the contributions of the codewords with $\ell \approx d - \ell$ may be neglected in our approximation.

To obtain $\mathbb{A}'_c(d)$, based on $f(x)$, we first generate the set consisting of $a(x)$ s which yield the weight-2 and -3 PCs, *i.e.* $\mathbb{A}_h(2) \cup \mathbb{A}_h(3)$. Next, for each $a(x) \in \mathbb{A}_h(2) \cup \mathbb{A}_h(3)$, we determine the corresponding SC $b(x) = a(x)g(x)$. Similarly, we determine the PC $h(x) = a(x)f(x)$ for each $a(x)$ in the set $\mathbb{A}_b(2) \cup \mathbb{A}_b(3)$ obtained based on $g(x)$. Finally, we narrow down the corresponding codewords as $w_H(b(x)) + w_H(h(x)) \leq d_{\text{free}+1}$ for $a(x) \in \mathbb{A}_h(2) \cup \mathbb{A}_h(3) \cup \mathbb{A}_b(2) \cup \mathbb{A}_b(3)$.

As examples, in Table IV, V and VI, we listed the low-weight PCs and SCs found by our proposed method for the codes listed in Table III with the corresponding example numbers where each polynomial appeared in.

B. Numerical results

We obtained the approximated union bound by (29) for the codes listed in Table III and compared them with that obtained using the transfer function in Figures 1-3. For reference purpose, the details of the PCs and SCs used for drawing the bound are listed in Tables IV - VI with the extra codewords found by computer search (labelled as 'Not Found').

In these figures, we also evaluated BER through computer simulations. To plot BER points, we assume each RSC code is BPSK modulated and transmitted over the AWGN channel with a frame with size of $N = 64$. At the receiver, the Viterbi algorithm is used to recover the transmitted bits and we accumulated more than 1,000 bits errors for obtain each plot point.

Fig. 1: Old Bound vs New Bound vs Simulation for 5/7 RSC Code

As shown in Table IV, since the free distance of the 5/7 RSC code is 5, the codewords consisting of weights 2 and 3 SCs or PCs are taken into account in the proposed method, thus all codewords with weights up to 6 are picked up. Also, Fig. 1 indicates that the union bound obtained using the codewords with weights up to $d_{\text{free}+1}$ tracks the BER curve with sufficient accuracy, especially in the high E_b/N_0 region. Moreover, the bounds obtained by our method and the transfer function converge to the same value with E_b/N_0 increment and match the simulation results well.

TABLE II: $a(x)$ and $h(x)$ for various $f(x)$

$f(x)$	weight	$a(x)$	$h(x)$

	3	1 $1 + x + x^5$ $1 + x + x^2 + x^3 + x^4 + x^6 + x^8$	$1 + x + x^5$ $1 + x^2 + x^{10}$ $1 + x^{11} + x^{13}$

TABLE III: The generator polynomials

	$f(x)$	$g(x)$
Code I (5/7)	$1 + x^2$ (Ex. 4)	$1 + x + x^2$ (Ex. 1)
Code I (37/21)	$1 + x + x^2 + x^3 + x^4$ (Ex. 3)	$1 + x^4$ (Ex. 4)
Code III (23/35)	$1 + x + x^4$ (Ex. 2)	$1 + x^2 + x^3 + x^4$ (Ex. 5)

For the 37/21 RSC code, since the free distance of the code is 6, there is no counting omission in the proposed method for codewords with weight up to 7 and the BER curve can be well approximated using the codewords with weight 6 and 7 with a high accuracy at the high E_b/N_0 region.

Fig. 2: Old Bound vs New Bound vs Simulation for 37/21 RSC Code

For the code III, the free distance is 7 and the proposed method identifies 2 codewords with weight-7 while 3 codewords with weight-8 can not be found as shown in Table VI. Thus, while we use the weight-7 codewords to approximate the BER curve as Fig. 3, there about a 0.1 dB gap between the proposed method and simulation results.

VI. CONCLUSION

In this paper, we proposed a method to determine the patterns of low-weight codewords of an RSC code. We established the low-weight codewords by identifying codewords with SCs or PCs of weight-2 and weight-3. Finally, we validated our proposed method by obtaining a union bound using the established low-weight codewords and compared it with that obtained via the transfer function method and the BER curve drawn from simulation results.

TABLE IV: SCs and PCs for Code I

$w_H(c(x))$		$a(x)$	$b(x)$	$h(x)$
5	Found	1	$1 + x + x^2$	$1 + x^2$
6	Found	$1 + x$	$1 + x^3$	$1 + x + x^2 + x^3$
		$1 + x^2$	$1 + x + x^3 + x^4$	$1 + x^4$
		$1 + x + x^2$	$1 + x^2 + x^4$	$1 + x + x^3 + x^4$
		$1 + x + x^3$	$1 + x^4 + x^5$	$1 + x + x^2 + x^5$

TABLE V: SCs and PCs for Code II

$w_H(c(x))$		$a(x)$	$b(x)$	$h(x)$
6	Found	$1 + x$	$1 + x + x^4 + x^5$	$1 + x^5$
7	Found	1	$1 + x^4$	$1 + x + x^2 + x^3 + x^4$

Fig. 3: Old Bound vs New Bound vs Simulation for 23/35 RSC Code

TABLE VI: SCs and PCs for Code III

$w_H(c(x))$		$a(x)$	$b(x)$	$h(x)$
7	Found	1	$1 + x^2 + x^3 + x^4$	$1 + x + x^4$
		$1 + x^2 + x^3$	$1 + x^7$	$1 + x + x^2 + x^6 + x^7$
8	Not Found	$1 + x$	$1 + x + x^2 + x^5$	$1 + x^2 + x^4 + x^5$
		$1 + x + x^2 + x^4$	$1 + x + x^7 + x^8$	$1 + x^3 + x^6 + x^8$
		$1 + x + x^2 + x^4 + x^6 + x^7$	$1 + x + x^6 + x^{11}$	$1 + x^3 + x^{10} + x^{11}$
