Abstract

In this paper,we present a novel low-complexity method for determining the distance spectrum of any RSC code that has the added benefit of revealing the pattern of the low-weight codewords. Using our method, we list the partial distance spectrum for selected RSC codes up to a cut-off weight $d_{\max}$ and compare the simulation results to the bounds obtained via our novel method and the transfer function method.

I. INTRODUCTION

The *turbo code* (TC) [**?**], introduced by Claude Berrou in 1993 is one of the forward-error correcting codes that comes very close to satisfying the Shannon limit for AWGN channels. Due to its excellent performance, TCs have been used in many applications and adopted as the channel code for the LTE standard, IEEE 802.16 WiMAX (worldwide interoperability for microwave access) and DVB-RCS2 (2nd generation digital video broadcasting - return channel via satellite) standards [**?**].

The simplest and most common construction of a TC is to concatenate two *recursive systematic convolutional* (RSC) codes (usually of the same kind) parallely via an interleaver. One of the many reasons why the TC excels as a channel code is its ability to map low-weight parity-check sequences in the first component RSC code to high-weight parity-check sequences in the second component RSC code using an interleaver, which in turn generates TCs with a large minimum distance value.

The design of a good deterministic interleaver requires the complete knowledge of all the low-weight codeword component patterns in the RSC code and missing even one of these patterns can result in deterministic interleavers that generate TCs with sub-par error correction performance. The transfer function of an RSC code is an interleaver design tool that provides information about the different weights in the code, as well as their corresponding multiplicities (distance spectrum). However, it provides no information with regards to the pattern of the low-weight codeword components. As an added downside, the complexity of calculating the transfer function for a given RSC code increases with the number of states and other methods such as Mason's Rule [**?**] have to be used. To the best of our knowledge, there exists no interleaver design tool that provides knowledge of both the distance spectrum and the low-weight codeword component patterns. Because of this, many of the interleaver design methods end up completely ignoring certain important low-weight codewords. In [**?**] for example, the interleaver design method does not take into account the existence of low-weight codewords with systematic components of weight 3, especially for the $5/7$ RSC code, where such codewords are very dominant.

In this paper, we present a novel method that can be used to find the distance spectrum of an RSC code as well as the pattern of the low-weight codeword components. The complexity of our method is independent of the number of states of the RSC code and its ability to reveal low-weight codeword patterns of an RSC code makes it an excellent tool for use in interleaver

design.

In order to validate our method, we generate a partial distance spectrum for specific RSC codes and compare it to the lower bound obtained via the transfer function method. We also compare the bounds obtained using our novel method to simulation results. In both cases, it is observed that the values begin to converge as E_b/N_0 increases.

The remainder of the research paper is organised as follows. Notations and definitions used in the research paper are introduced in Section II. In Section III, we discuss the distance spectrum and union bound of RSC codes and present the theory behind our novel method for obtaining the distance spectrum. Moving on to Section IV, we use our novel method to determine low-weight parity check patterns. Comparison of bounds obtained using our novel method to that obtained using the transfer function as well as simulation results are presented in Section VI and the paper concludes in Section **??**.

II. PRELIMINARIES

A polynomial in x with degree M is an expression of the form

$$v(x) = \sum_{m=0}^{M} v_m x^m \tag{1}$$

where v_m, $0 \leq m \leq M$, are called the *coefficients* and $v_M \neq 0$. If $v_M = 1$, $v(x)$ is called the *monic* polynomial. We call the total number of non-zero coefficients the *Hamming weight* of $v(x)$, and write $w_H(v(x))$.

For a prime number p, if the addition and multiplication of two elements in the integer set $\{0, 1, p-1\}$ are performed on the terms $\mathrm{mod} p$, we call the set the Galois field and denoted as $\mathrm{GF}(p)$. If the coefficients in (1) are elements of $\mathrm{GF}(p)$, $v(x)$ is called *polynomial over* $\mathrm{GF}(p)$.

For two polynomials $v(x)$ and $w(x)$ with degrees M and N, respectively, the addition and multiplication over $\mathrm{GF}(p)$ are defined as

$$v(x) + w(x) = \sum_{m=0}^{\max\{M,N\}} [(v_m + w_n) \mod p] x^m \tag{2}$$

and

$$v(x)w(x) = \sum_{m=0}^{M+N} \sum_{i=0}^{m} [v_i w_{m-i} \mod p] x^m \tag{3}$$

respectively. A monic polynomial which cannot be represented by multiplication of some lower degree polynomials is called a *prime polynomial*. For two polynomials $v(x)$ and $w(x)$ over $\mathrm{GF}(p)$, we assume $w(x) \neq 0$. Then there exists polynomials $q(x)$ and $r(x)$ over $\mathrm{GF}(p)$ such that

$$v(x) = w(x)q(x) + r(x) \tag{4}$$

with $\deg(r(x)) < \deg(w(x))$. $r(x)$ in the expression (4), is denoted by

$$r(x) = v(x) \mod w(x) \tag{5}$$

is called the *remainder polynomial* while $q(x)$ is called the *quotient polynomial* of the division of $v(x)$ by $w(x)$.

Let $v(x)$ be a prime polynomial over $\mathrm{GF}(p)$ with $\deg(v(x)) := M > 1$ and $\mathcal{V}$ be the set of size p^M consisting of all polynomials over $\mathrm{GF}(p)$ with degree less than M. Then, the *extension field of* $\mathrm{GF}(p)$, denoted by $\mathrm{GF}\left(p^M\right)$, is the set $\mathcal{V}$ with addition and multiplication over $\mathrm{GF}(p)$ where the multiplication is carried out modulo-$v(x)$ over $\mathrm{GF}(p)$. Each non-zero elements in $\mathrm{GF}\left(p^M\right)$ can be represented by a power of X uniquely as X^m, $0 \leq m \leq p^M - 1$.

For each non-zero element of $\mathrm{GF}\left(p^M\right)$, there exist integers ϵ such that $X^\epsilon = 1$ and the least positive integer among them is called the *order* of X. The element with order $\epsilon = p^M - 1$ is called *primitive element*. For $\mathrm{GF}\left(p^M\right)$ generated by a prime polynomial $v(x)$ with $\deg(v(x)) = M$, if X is a primitive element in $\mathrm{GF}\left(p^M\right)$, then $v(x)$ is called *primitive polynomial*. Finally, the root of $v(x)$, is the non-zero element in $\varphi \in \mathrm{GF}\left(p^M\right)$ such that $v(\varphi) = 0$. If $v(x)$ is a primitive polynomial, the order of φ is $\epsilon = p^M - 1$ while $\epsilon | p^M - 1$ otherwise. Moreover, the elements φ^i, $0 \le i \le \epsilon - 1$, are all distinct each other.

III. The Characteristics of the Low-weights Codewords of RSC code

The outputs of an RSC code are determined by the input bit sequence $b(x)$, the states of the shift registers and the feedforward and feedback connections of shift registers that can be represented by a generator function.

As an instance, the generator function of a rate $1/2$ RSC code may be written as

$$\left[1 \quad \frac{f(x)}{g(x)} \right]$$

where 1 yields the *systematic component* (SC) $b(x)$ while the *parity-check component* (PC) $h(x)$ is associated with the feedforward and feedback connections of the shift registers, specified by $f(x)$ and $g(x)$, respectively. Each output $c(x)$ is a mixture of the SC and PC as

$$c(x) = b(x^2) + xh(x^2) \tag{6}$$

where

$$h(x) = f(x)g^{-1}(x)b(x) \tag{7}$$

From (6), it is trivial that

$$w_H(c(x)) = w_H(b(x)) + w_H(h(x)) \tag{8}$$

and hence, each low-weight codeword is a conjunction of two low-weight SC and PC.

Under the assumption of large frame sizes, the presence of $g^{-1}(x)$ in (7) may involve a particular sequence of bits that is repeated a large number of times, hence a high-weight PC. A low-weight PC occurs if and only if

$$b(x) \bmod g(x) \equiv 0 \tag{9}$$

The inputs $b(x)$ which meet the condition in (9) is called a *return-to-zero* (RTZ) input. Thus, every RTZ input can be factorized by

$$b(x) = a(x)g(x) \tag{10}$$

Substituting (10) into (7), we can characterize the low-weight PC as

$$h(x) = f(x) \cdot g^{-1}(x) \cdot a(x)g(x)$$
$$= a(x)f(x) \tag{11}$$

Finally, for a given RSC code, we can formulate our goal as, to find all $a(x)$s which satisfy (10) and (11) simultaneously. However, since there is no essential mathematical difference between the two equations, in the next section, we present a method for determining the low-weight PC patterns for $2 \leq w_H(h(x)) \leq 3$

IV. THE PATTERNS OF THE LOW-WEIGHT PCS

To determine the details of the patterns of the low-weight PCs, we assume $f(x)$ can be factorized into K prime polynomials as

$$f(x) = \prod_{k=0}^{K-1} f_k^{\gamma_k}(x) \tag{12}$$

where $\gamma_0, \gamma_1, \cdots, \gamma_{K-1}$ are positive integers and we assume φ_k is a root of $f_k(x)$ of order ϵ_k.

Refering (11), we consider the solution of

$$h(x) \mod f(x) \equiv 0 \tag{13}$$

We start from the simplest case $K = 1$, *i.e.*, $f(x) = f_0^{\gamma_0}(x)$. Then, we can see from (11) that each root is also a root of $h(x)$. For the case $\gamma_0 = 1$, since all φ_0^i, $0 \le i < \epsilon_0$, are distinct from each other, the condition

$$h(\varphi_0^i) = 0, \quad 0 \le i < \epsilon_0 \tag{14}$$

is necessary and sufficient to fulfil (13). For $\gamma_0 > 1$, on the other hand, (14) is necessary but not sufficient for (13). For this case, although we may derive some solutions by differential equations

$$\left. \frac{d^{(j)} h(x)}{dx^j} \right|_{x = \varphi_0^i} = 0, \quad 0 \le i < \epsilon_0, \ 1 \le j < \gamma_0 \tag{15}$$

we can not determine the patterns completely, since the operations on coefficients of the polynomial are performed on the terms $\mod p$. Thus, we need to remove the ghost solutions by careful confirmation.

By repeating the above discussion for the roots φ_k, $0 < k < K$, and taking the intersection of the results, we can easily extend to the case $K > 1$.

A. *The patterns of the weight-2 PCs*

Each weight-2 PC can be written as

$$h(x) = 1 + x^\alpha \tag{16}$$

without loss of generality. Thus, we have from (14) that

$$(\varphi_0^i)^\alpha = 1, \quad 0 \le i < \epsilon_0 \tag{17}$$

On the other hand, the order ϵ_0 is the least integer satisfying $\varphi_0^{\epsilon_0} \equiv 1$, thus, α should satisfy the condition

$$\alpha \mod \epsilon_0 \equiv 0 \tag{18}$$

B. The patterns of the weight-3 PCs

Each weight-3 PC can be written as

$$h(x) = 1 + x^\alpha + x^\beta, \ \alpha < \beta \tag{19}$$

without loss of generality. Thus, (α, β) should satisfying the condition

$$\varphi_0^\alpha + \varphi_0^\beta = 1 \tag{20}$$

Such pairs can be found by referring to the table of the extended field for $GF(2^M)$. Let (m, n) be such a pair, then it is obvious that all pairs $(\alpha, \ \beta)$ that satisfy

$$X^m + X^n = 1, \ (m, n) \equiv (\alpha, \ \beta) \bmod \epsilon_0 \tag{21}$$

also satisfy (20), where $(\alpha, \ \beta) \bmod \epsilon_0$ is shorthand for the operation $(\alpha \bmod \epsilon_0, \ \beta \bmod \epsilon_0)$. On the other hand, for a fixed α, since $\alpha + i, \ 0 \le i < \epsilon_0$, are distinct from each other, any integer β that satisfies (20) must be such that $n \equiv \beta \bmod \epsilon_0$.

Furthermore, let $\mathcal{M} = \epsilon_0 \ell_0 + m$ and $\mathcal{N} = \epsilon_0 \ell_1 + n, \ \ell_0, \ell_1 \ge 0$. We denote the set of all pairs as $\mathcal{M} \bar{\otimes} \mathcal{N}$, where the elements of this set are formed using a tensor product approach. Then, $(\alpha, \ \beta) \in \mathcal{M} \bar{\otimes} \mathcal{N}$

C. Examples

Example 1. $f(x) = 1 + x + x^2$

$f(x)$ is a primitive polynomial and since $x^1 = x$, $x^2 \equiv 1 + x$, and $x^3 \equiv 1 \bmod f(x)$, the order of the root φ_0 is $\epsilon_0 = 3$.

Weight-2 PCs: From (18), it is obvious that α should be a multiple of 3. The corresponding values for $a(x)$ and $h(x)$ are shown in Table I for the first four valid values of α. We may write

TABLE I: $f(x) = 1 + x + x^2$

$a(x)$	$h(x)$
$1 + x$	$1 + x^3$
$1 + x + x^3 + x^4$	$1 + x^6$
$1 + x + x^3 + x^4 + x^6 + x^7$	$1 + x^9$
$1 + x + x^3 + x^4 + x^6 + x^7 + x^9 + x^{10}$	$1 + x^{12}$

the weight-2 PCs in general form as $h(x) = 1 + x^{3\ell}$, $\ell > 1$ and the corresponding $a(x)$ is given by

$$a(x) = \sum_{i=0}^{\ell-1} x^{3i}(1+x)$$

Weight-3 PCs: The elements of $GF(2^2)$ are shown in Table II. From this table we have $(m,n) = (1,2)$ and consequently, $(\alpha, \beta) \in \{3\ell_0+1\} \bar{\otimes} \{3\ell_1+2\}$, $\ell_0, \ell_1 \geq 0$. The corresponding values for $a(x)$ and $h(x)$ are shown in Table III below for the first four valid values of (α, β).

TABLE II: Non-zero Elements of GF (2^2) generated by $f(x) = 1 + x + x^2$

power representation	actual value
$X^0 = X^3 = 1$	1
X	x
X^2	$1+x$

TABLE III: $f(x) = 1 + x + x^2$

$a(x)$	$h(x)$
1	$1 + x + x^2$
$1 + x + x^2$	$1 + x^2 + x^4$
$1 + x + x^3$	$1 + x^4 + x^5$
$1 + x^2 + x^3$	$1 + x + x^5$

We may write the weight-3 PCs in general form as $h(x) = 1 + x^{3\ell_0+1} + x^{3\ell_1+2}$, $\ell_0, \ell_1 \geq 0$

Example 2. $f(x) = 1 + x + x^2 + x^3 + x^4$

$f(x)$ is a prime but not primitive, and it can be confirmed that the order of φ_0 is $\epsilon_0 = 5$.

Weight-2 PCs: From (18), α should be a multiple of 5. The corresponding values for $a(x)$ and $h(x)$ are shown in Table IV with general forms for $\ell > 1$

TABLE IV: $f(x) = 1 + x + x^2 + x^3 + x^4$

$\alpha(x) = \sum_{i=0}^{\ell-1} x^{5i}(1+x)$	$h(x) = 1 + x^{5\ell}$
$1 + x$	$1 + x^5$
$1 + x + x^5 + x^6$	$1 + x^{10}$
$1 + x + x^5 + x^6 + x^{10} + x^{11}$	$1 + x^{15}$
$1 + x + x^5 + x^6 + x^{10} + x^{11} + x^{15} + x^{16}$	$1 + x^{20}$

Weight-3 PCs: We refer to Table V and it is obvious that $(\alpha, \beta) = \emptyset$ and therefore, there are no weight-3 PCs for $f(x)$

TABLE V: Non-zero Elements of $\mathrm{GF}(2^4)$ generated by $f(x) = 1 + x + x^2 + x^3 + x^4$

power representation	polynomial representation
$X^0 \ = X^5 \ = X^{10} \ = X^{15}$	1
$X \ = X^6 \ = X^{11}$	x
$X^2 \ = X^7 \ = X^{12}$	x^2
$X^3 \ = X^8 \ = X^{13}$	x^3
$X^4 \ = X^9 \ = X^{14}$	$1 + x + x^2 + x^3$

Example 3. $f(x) = 1 + x^2$

We can write $f(x)$ as

$$f(x) = (1 + x)^2$$

and the order of the root $\varphi_0 = 1$ is $\epsilon_0 = 1$.

Weight-2 PCs: Since We obtain from (14) and (15)

$$(\varphi_0)^\alpha = 1 \tag{22}$$

$$\alpha(\varphi_0)^{(\alpha-1)} = 0 \tag{23}$$

Although (22) indicates α (from (18)) can be any positive integer, we can see from (23) that α should be an even number. The corresponding values for $a(x)$ and $h(x)$ are shown in Table VI with general forms for $\ell > 1$.

Weight-3 PCs: Given that there is a single non-zero element in GF(2) which is generated by $1 + x$ we can conclude that there are no weight-3 PCs associated with $f(x)$.

TABLE VI: $f(x) = 1 + x^2$

$\alpha(x) = \sum_{i=0}^{\ell-1} x^{2i}$	$h(x) = 1 + x^{2\ell}$
1	$1 + x^2$
$1 + x^2$	$1 + x^4$
$1 + x^2 + x^4$	$1 + x^6$
$1 + x^2 + x^4 + x^6$	$1 + x^8$

————————

Example 4. $f(x) = 1 + x^2 + x^3 + x^4 + x^6$

$f(x)$ can be written as

$$f(x) = \prod_{k=0}^{1} f_k(x)$$

where

$$f_0(x) = 1 + x + x^2, \ f_1(x) = 1 + x + x^2 + x^3 + x^4$$

From Example 1 and Example 2, we know that $\alpha_0 = 3$ and $\alpha_1 = 5$.

Weight-2 PCs: From (18) , the valid values of α should be a multiple of the least common multiples of α_0 and α_1, which means α should be a multiple of 15. The corresponding values for $a(x)$ and $h(x)$ are shown in Table VIII with general forms for $\ell > 1$.

TABLE VII: $f(x) = 1 + x^2 + x^3 + x^4 + x^6$

$\alpha(x) = \sum_{i=0}^{\ell-1} x^{15i}(1 + x^2 + x^3 + x^6 + x^7 + x^9)$	$h(x) = 1 + x^{15\ell}$
$1 + x^2 + x^3 + x^6 + x^7 + x^9$	$1 + x^{15}$
$1 + x^2 + x^3 + x^6 + x^7 + x^9 + x^{15} + x^{17} + x^{18} + x^{21} + x^{22} + x^{24}$	$1 + x^{30}$

Weight-3 PCs: Since $f(x)$ from Example 2 does not yield any weight-3 PC, there are no weight-3 PCs associated with $f(x)$.

Example 5. $f(x) = 1 + x + x^5$

$f(x)$ can be written as

$$f(x) = \prod_{k=0}^{1} f_k(x)$$

where

$$f_0(x) = 1 + x + x^2, \ f_1(x) = 1 + x^2 + x^3$$

From Example 1, we know that $\alpha_0 = 3$ and it can be confirmed that $\alpha_1 = 7$.

Weight-2 PCs: From (18), the valid values of α should be a multiple of the least common multiples of α_0 and α_1, which means α should be a multiple of 21. The corresponding values for $a(x)$ and $h(x)$ are shown in Table VIII with general forms for $\ell > 1$.

TABLE VIII: $f(x) = 1 + x + x^5$

$\alpha(x) = \sum_{i=0}^{\ell-1} x^{21i}(1 + x^2 + x^3 + x^4 + x^6 + x^8 + x^4 + x^6 + x^8 + x^{11} + x^{12} + x^{16})$	$h(x) = 1 + x^{21\ell}$
$1 + x^2 + x^3 + x^4 + x^6 + x^8 + x^4 + x^6 + x^8 + x^{11} + x^{12} + x^{16}$	$1 + x^{21}$

Weight-3 PCs: From Example 1, we have $(\alpha_0, \ \beta_0) \in \{3\ell_0 + 1\} \ \bar{\otimes} \ \{3\ell_1 + 2\}$, $\ell_0, \ell_1 \geq 0$ and Table IX indicates that,

$$(\alpha_1, \ \beta_1) \in \{7\ell_2 + 1\} \ \bar{\otimes} \ \{7\ell_3 + 5\}$$
$$\bigcup \{7\ell_2 + 2\} \ \bar{\otimes} \ \{7\ell_3 + 3\}$$
$$\bigcup \{7\ell_2 + 4\} \ \bar{\otimes} \ \{7\ell_3 + 6\}$$

$\ell_2, \ell_3 \geq 0$. Therefore $(\alpha, \beta) \in (\alpha_0, \ \beta_0) \ \bigcap \ (\alpha_1, \ \beta_1)$.

TABLE IX: Non-zero Elements of $\mathrm{GF}(2^3)$ generated by $1 + x^2 + x^3$

power representation	actual value
$X^0 \ = X^7$	1
X	x
X^2	x^2
X^3	$1 + x^2$
X^4	$1 + x + x^2$
X^5	$1 + x$
X^6	$x + x^2$

The corresponding values for $a(x)$ and $h(x)$ are shown in Table X below for the first three valid values of (α, β). Also, a visual for $(\alpha, \ \beta)$ is shown in Fig. 1, where the union is in dicated by the pairs connected in Fig. 1-(a) and Fig. 1-(b).

TABLE X: $f(x) = 1 + x + x^5$

$a(x)$	$h(x)$

V. Codeword Component Pattern List and the Union Bound

In this section, we outline our method for obtaining the list of all low weight codewords for a given RSC code.

Let $\mathcal{A}_h(d)$ be the set of all $a(x)$ which yields weight-d parity-check component *i.e.*, $w_H(h(x)) = w_H(a(x)f(x)) = d$ for $a(x) \in \mathcal{A}_h(d)$. Similarly $\mathcal{A}_b(d)$ is the set of all $a(x)$ which yields weight-d systematic component *i.e.*, $w_H(b(x)) = w_H(a(x)g(x)) = d$ for $a(x) \in \mathcal{A}_b(d)$ and $\mathcal{A}_c(d)$ is the set of all $a(x)$ which yields weight-d codeword *i.e.*, $w_H(c(x)) = w_H(a(x)f(x)) + w_H(a(x)g(x)) = d$ for $a(x) \in \mathcal{A}_c(d)$.

From (8), when $w_H(b(x)), w_H(h(x)) \geq 2$, we have

$$\mathcal{A}_c(d) = \bigcup_{\ell=2}^{d-2} \{\mathcal{A}_b(\ell) \cap \mathcal{A}_h(d - \ell)\} \tag{24}$$

However, to determine $\mathcal{A}_b(\ell)$ or $\mathcal{A}_h(\ell)$ for a large ℓ is a complex task in general. Thus, in this

paper, we replace the set $\mathcal{A}_c(d)$ by the approximated set $\mathcal{A}'_c(d)$ as defined in (25)

$$\mathcal{A}_c(d) \approx \mathcal{A}'_c(d) = \left\{ \bigcup_{\ell=2}^{\ell+\alpha} \{\mathcal{A}_b(\ell) \cap \mathcal{A}_h(d-\ell)\} \right\} \bigcup$$
$$\left\{ \bigcup_{\ell=2}^{\ell+\alpha} \{\mathcal{A}_b(d-\ell) \cap \mathcal{A}_h(\ell)\} \right\} \tag{25}$$

where some codewords in $\mathcal{A}_c(d)$ with $\ell \approx d - \ell$ may be ignored in $\mathcal{A}'_c(d)$.

Example 6. If we set $d = 8$ and $\alpha = 1$, $\mathcal{A}'_c(8)$ becomes

$$\mathcal{A}'_c(8) = \left\{ \{\mathcal{A}_b(2) \cap \mathcal{A}_h(6)\} \bigcup \{\mathcal{A}_b(3) \cap \mathcal{A}_h(5)\} \right\} \bigcup$$
$$\left\{ \{\mathcal{A}_b(6) \cap \mathcal{A}_h(2)\} \bigcup \{\mathcal{A}_b(5) \cap \mathcal{A}_h(3)\} \right\}$$

We can see that $\{\mathcal{A}_b(4) \cap \mathcal{A}_h(4)\}$ is not used in $\mathcal{A}'_c(8)$, event though it is used in $\mathcal{A}_c(8)$.

Once we obtain the set

$$\bigcup_{d=d_{\min}}^{d_{\max}} \mathcal{A}'_c(d)$$

, we can list the low weight codeword component patterns for a given RSC code using (10) and (11).

In order to validate our novel method, we can calculate the lower bound for each RSC code by modifying the union bound of the bit-error rate equation in [?], which gives us

$$P_b \leq \frac{1}{k} \sum_{d=d_{\text{free}}}^{d_{\max}} \sum_{a(x) \in \mathcal{A}'_c(d)} w_H(a(x)g(x))Q\left(\sqrt{\frac{2dE_c}{N_0}}\right) \tag{26}$$

VI. SIMULATION AND THEORETICAL RESULTS

In this section, we compare the bounds obtained via our novel method to bounds obtained using the transfer function method as well as the simulation results for the $5/7$, $37/21$ and $23/35$ RSC codes, each with a frame size $N = 64$.

We set $d_{\max} = d_{\min} + 3$ and using our novel method outlined in the previous section, we obtained the low-weight codeword component patterns for each RSC code and the results are shown in Tables XI, XII and XIII respectively. We then calculate the lower bounds for our novel method and the transfer function using (26) and its original version in [**?**] respectively.

TABLE XI: Partial Codeword Component Pattern Distance Spectrum for the $5/7$ RSC code, $d_{\text{free}} = 5$

| $w_H(c(x))$	$a(x)$	$b(x)$	$h(x)$
5	1	$1 + x + x^2$	$1 + x^2$
6	$1 + x^2$	$1 + x + x^3 + x^4$	$1 + x^4$
	$1 + x$	$1 + x^3$	$1 + x + x^2 + x^3$
	$1 + x^2 + x^4$	$1 + x + x^3 + x^5 + x^6$	$1 + x^6$
7	$1 + x^2 + x^3$	$1 + x + x^5$	$1 + x^3 + x^4 + x^5$
	$1 + x + x^2$	$1 + x^2 + x^4$	$1 + x + x^3 + x^4$
	$1 + x + x^3$	$1 + x^4 + x^5$	$1 + x + x^2 + x^5$
8	$1 + x^2 + x^4 + x^6$	$1 + x + x^3 + x^5 + x^7 + x^8$	$1 + x^8$
	$1 + x + x^3 + x^4$	$1 + x^6$	$1 + x + x^2 + x^4 + x^5 + x^6$

Fig. 2: Old Bound vs New Bound vs Simulation for 5/7 RSC Code

Fig. 2 shows the simulation results for the $5/7$ RSC code as well as the lower bounds obtained using the transfer function as well as our novel method. The feedforward connection has the

polynomial representation $1 + x^2$ and can be factorized into the irreducible polynomial $1 + x$. From Example 3, we observe that whiles there exists weight-2 PCs, there are no weight-3 PCs for $1 + x^2$ The feedback connection has the polynomial representation $1 + x + x^2$, which is an irreducuble polynomial and from Example 1, we can confirm that there exists weight-2 SCs as well as weight-3 SCs. In Fig. 2, we observe that there is some difference between the new (novel method) bound and the old (transfer function) bound, but they tend to converge as E_b/N_0 increases. This suggests that the approximation $\bigcup_{d=d_{\min}}^{d_{\max}} \mathcal{A}'_c(d)$ used in our novel method is sufficient for the $5/7$ RSC code.

TABLE XII: Partial Codeword Component Pattern Distance Spectrum for the $37/21$ RSC code, $d_{\text{free}} = 6$

| $w_H(c(x))$	$a(x)$	$b(x)$	$h(x)$
6	$1 + x$	$1 + x + x^4 + x^5$	$1 + x^5$
7	1	$1 + x^4$	$1 + x + x^2 + x^3 + x^4$
8	$1 + x + x^5 + x^6$	$1 + x + x^4 + x^6 + x^9 + x^{10}$	$1 + x^{10}$

Fig. 3: Old Bound vs New Bound vs Simulation for 37/21 RSC Code

Fig. 3 shows the simulation results for the $37/21$ RSC code as well as the lower bounds obtained using the transfer function as well as our novel method. The feedforward connection has the polynomial representation $1 + x + x^2 + x^3 + x^4$, which is an irreducible polynomial. From Example 2, we confirm that whiles weight-2 PCs exist, there are no wight-3 PCs. The feedback connection has the polynomial representation $1 + x^4$, and from Example 3, we can deduce that weight-2 SCs exist, but there are no weight-3 SCs. In Fig. 3, we observe that there is some difference between the new (novel method) bound and the old (transfer function) bound, but

they tend to converge as E_b/N_0 increases. This suggests that the approximation $\bigcup_{d=d_{\min}}^{d_{\max}} \mathcal{A}'_c(d)$ used in our novel method is also sufficient for the $37/21$ RSC code.

TABLE XIII: Partial Codeword Component Pattern Distance Spectrum for the $23/35$ RSC code, $d_{\text{free}} = 7$

| $w_H(c(x))$	$a(x)$	$b(x)$	$h(x)$
7	$1 + x^2 + x^3$	$1 + x^7$	$1 + x + x^2 + x^6 + x^7$
	1	$1 + x^2 + x^3 + x^4$	$1 + x + x^4$
8	$1 + x + x^2 + x^3 + x^5$	$1 + x^3 + x^4 + x^8 + x^9$	$1 + x^7 + x^9$
9	$1 + x + x^2 + x^3 + x^5 + x^7 + x^8$	$1 + x + x^3 + x^4 + x^7 + x^{12}$	$1 + x^{11} + x^{12}$
10	$1 + x^2 + x^3 + x^7 + x^9 + x^{10}$	$1 + x^{14}$	$1 + x + x^2 + x^6 + x^8 + x^9 + x^{13} + x^{14}$

Fig. 4: Old Bound vs New Bound vs Simulation for $23/35$ RSC Code

Fig. 4 shows the simulation results for the $23/35$ RSC code as well as the lower bounds obtained using the transfer function as well as our novel method. The feedforward connection has the polynomial representation $1 + x + x^4$, which is similar in characteristic to the polynomial in Example 1. It can easily be confirmed that there exists weight-2 and weight-3 PCs. For the weight-2 PCs, the general form for $a(x)$ is

$$a(x) = \sum_{\ell=0}^{L-1} x^{15\ell}(1 + x + x^2 + x^3 + x^5 + x^7 + x^8 + x^{11})$$

and since it yields codewords such that $w_H(c(x)) > d_{\max}$, there are not included in our approximation of the lower bound, as can be observed from Table XII. The feedback connection has the polynomial representation $1 + x^2 + x^3 + x^4$, which can be factorized into 2 irreducible

polynomials and it can easily be confirmed that there exists no weight-3 SCs, since $1 + x$ is a factor. In Fig. 4, we observe that the old (transfer function) bounds and simulation results converge as the E_b/N_0 value increases. However, there is some difference between the new (novel method) bound and the old (transfer function) bound, even as E_b/N_0 increases. This suggests that the approximation used in our novel method is insufficient for this $23/35$ RSC code and considering $w_H(h(x)),\ w_H(b(x)) = 4$ might yield a more accurate bound.
